- <!DOCTYPE html> declaration is used to specify the version of HTML that a web page is using. It is not an HTML tag; instead, it is a document type declaration (DTD) that helps browsers render the page correctly.

- <head> element is a container that holds meta-information about an HTML document. This meta-information includes details such as the document's title, character set encoding, linked stylesheets, scripts, and other metadata that isn't directly displayed on the web page.

- <body> element defines the structure and presentation of the webpage. It is the part of the HTML document that users see and interact with when they visit a website.

- <footer> element is used to define the footer section of a webpage. The footer typically contains information about the document, such as copyright information, links to related documents, authorship details, and contact information. The content within the <footer> element is placed at the bottom of the webpage and is separate from the main content in the <body>.
